

CSE252B_WI24_assignment_4

February 21, 2024

1 CSE 252B: Computer Vision II, Winter 2024 – Assignment 4

Instructor: Ben Ochoa

Assignment due: Wed, Mar 6, 11:59 PM

Name:

PID:

1.1 Instructions

- Review the academic integrity and collaboration policies on the course website.
- This assignment must be completed individually.
- All solutions must be written in this notebook.
- Math must be done in Markdown/L^AT_EX.
- You must show your work and describe your solution.
- Programming aspects of this assignment must be completed using Python in this notebook.
- Your code should be well written with sufficient comments to understand, but there is no need to write extra markdown to describe your solution if it is not explicitly asked for.
- This notebook contains skeleton code, which should not be modified (this is important for standardization to facilitate efficient grading).
- You may use python packages for basic linear algebra, but you may not use functions that directly solve the problem. If you are uncertain about using a specific package, function, or method, then please ask the instructional staff whether it is allowable.
- **You must submit this notebook as an .ipynb file, a .py file, and a .pdf file on Gradescope.**
 - You may directly export the notebook as a .py file. You may use [nbconvert](#) to convert the .ipynb file to a .py file using the following command `jupyter nbconvert --to script filename.ipynb`
 - There are two methods to convert the notebook to a .pdf file.
 - * You may first export the notebook as a .html file, then print the web page as a .pdf file.
 - * If you have XeTeX installed, then you may directly export the notebook as a .pdf file. You may use [nbconvert](#) to convert a .ipynb file to a .pdf file using the following command `jupyter nbconvert --allow-chromium-download --to webpdf filename.ipynb`
 - **You must ensure the contents in each cell (e.g., code, output images, printed results, etc.) are clearly visible, and are not cut off or partially cropped in the .pdf file.**

- Your code and results must remain inline in the .pdf file (do not move your code to an appendix).
- **While submitting on gradescope, you must assign the relevant pages in the .pdf file submission for each problem.**
- It is highly recommended that you begin working on this assignment early.

2 Problem 1 (Programming): Feature detection (20 points)

Download input data from the course website. The file price_center20.JPG contains image 1 and the file price_center21.JPG contains image 2.

For each input image, calculate an image where each pixel value is the minor eigenvalue of the gradient matrix

$$N = \begin{bmatrix} \sum_w I_x^2 & \sum_w I_x I_y \\ \sum_w I_x I_y & \sum_w I_y^2 \end{bmatrix}$$

where w is the window about the pixel, and I_x and I_y are the gradient images in the x and y direction, respectively. Calculate the gradient images using the five-point central difference operator. Set resulting values that are below a specified threshold value to zero (hint: calculating the mean instead of the sum in N allows for adjusting the size of the window without changing the threshold value). Apply an operation that suppresses (sets to 0) local (i.e., about a window) non-maximum pixel values in the minor eigenvalue image. Vary these parameters such that 600–650 features are detected in each image. For resulting nonzero pixel values, determine the subpixel feature coordinate using the Förstner corner point operator.

You may use `scipy.signal.convolve` to perform convolution operation and `scipy.ndimage.maximum_filter` for NMS operation.

You may either directly use the color images for feature detection, or use the color to grayscale mapping $Y = 0.21263903R + 0.71516871G + 0.072192319B$ to convert the images to grayscale first.

Report your final values for:

- the size of the feature detection window (i.e., the size of the window used to calculate the elements in the gradient matrix N)
- the minor eigenvalue threshold value
- the size of the local nonmaximum suppression window
- the resulting number of features detected (i.e., corners) in each image.

Display figures for:

- minor eigenvalue images before thresholding
- minor eigenvalue images after thresholding
- original images with detected features

A typical implementation takes around 30 seconds to run. If yours takes more than 120 seconds, you may lose points.

2.1 Problem 2 (Programming): Feature matching (15 points)

Determine the set of one-to-one putative feature correspondences by performing a brute-force search for the greatest correlation coefficient value (in the range $[-1, 1]$) between the detected features in image 1 and the detected features in image 2. Only allow matches that are above a specified correlation coefficient threshold value (note that calculating the correlation coefficient allows for adjusting the size of the matching window without changing the threshold value). Further, only allow matches that are above a specified distance ratio threshold value, where distance is measured to the next best match for a given feature. Vary these parameters such that 160-240 putative feature correspondences are established. Optional: constrain the search to coordinates in image 2 that are within a proximity of the detected feature coordinates in image 1. The proximity is calculated using the subpixel coordinates of the detected feature coordinates in image 1 and image 2. Given (x_1, y_1) in image 1 and (x_2, y_2) in image 2, you can think of a square with side length p , centered at (x_2, y_2) . Then, (x_1, y_1) is within the proximity window if it lies inside that square.

Use the following formula to calculate the correlation coefficient (normalized cross correlation) between two image windows I_1 and I_2 :

$$\frac{\sum_{x,y} [I_1(x,y) - \bar{I}_1] [I_2(x,y) - \bar{I}_2]}{\sqrt{\sum_{x,y} [I_1(x,y) - \bar{I}_1]^2 \cdot \sum_{x,y} [I_2(x,y) - \bar{I}_2]^2}}$$

where $I(x, y)$ is the pixel value of I at (x, y) and \bar{I} is the mean value of I .

Note: You must center each window at the sub-pixel corner coordinates while computing normalized cross correlation, i.e., you must use bilinear interpolation to compute the pixel values at non-integer coordinates; otherwise, you will lose points.

Report your final values for:

- the size of the matching window
- the correlation coefficient threshold
- the distance ratio threshold
- the size of the proximity window (if used)
- the resulting number of putative feature correspondences (i.e., matched features)

Display figures for:

- pair of images, where the matched features in each of the images are indicated by a square window about the feature.

(You must use original (color) images to the draw boxes and correspondence lines)

A typical implementation takes around 10 seconds to run. If yours takes more than 120 seconds, you may lose points.

```
[ ]: from scipy.interpolate import RegularGridInterpolator

def bilinear_interpolation1(pts,I_gray,w):
    # inputs:
    # pts: center points
    # I_gray: grayscale converted input image
    # w: window size
    #

2.2 Problem 3 (Programming): Outlier Rejection (15 points)

The resulting set of putative point correspondences should contain both inlier and outlier correspondences (i.e., false matches). Determine the set of inlier point correspondences using the M-estimator Sample Consensus (MSAC) algorithm, where the maximum number of attempts to find a consensus set is determined adaptively. For each trial, you must use the 4-point algorithm (as described in lecture) to solve for the planar projective transformation from the 2D points in image 1 to the 2D points in image 2. Calculate the (squared) Sampson error as a first order approximation to the geometric error. There must be at least **150 inlier correspondences**.

hint: this problem has codimension 2

Report your values for:

- the probability p that at least one of the random samples does not contain any outliers
- the probability α that a given point is an inlier
- the resulting number of inliers
- the number of attempts to find the consensus set
- the tolerance for inliers
- the cost threshold

Display figures for:

- pair of images, where the inlier features in each of the images are indicated by a square window about the feature and a line segment is drawn from the feature to the coordinates of the corresponding feature in the other image

```

2.3 Problem 4 (Programming): Linear Estimate (15 points)

Estimate the planar projective transformation H_{DLT} from the resulting set of inlier correspondences using the direct linear transformation (DLT) algorithm (with data normalization). You must express $\mathbf{x}'_i = H\mathbf{x}_i$ as $[\mathbf{x}'_i]^\perp H\mathbf{x}_i = 0$ (not $\mathbf{x}'_i \times H\mathbf{x}_i = 0$), where $[\mathbf{x}'_i]^\perp \mathbf{x}'_i = 0$, when forming the solution. Return H_{DLT} , scaled such that $\|H_{\text{DLT}}\|_{\text{Fro}} = 1$

```

2.4 Problem 5 (Programming): Nonlinear Estimate (45 points)

Use H_{DLT} and the Sampson corrected points (in image 1) as an initial estimate to an iterative estimation method, specifically the sparse Levenberg-Marquardt algorithm, to determine the Maximum Likelihood estimate of the planar projective transformation that minimizes the reprojection error. You must parameterize the planar projective transformation matrix and the homogeneous 2D scene points that are being adjusted using the parameterization of homogeneous vectors.

Report the initial cost (i.e. cost at iteration 0) and the cost at the end of each successive iteration. Show the numerical values for the final estimate of the planar projective transformation matrix H_{LM} , scaled such that $\|H_{LM}\|_{Fro} = 1$.
