CSE252B WI24 assignment 3

February 7, 2024

1 CSE 252B: Computer Vision II, Winter 2024 – Assignment 3

Instructor: Ben Ochoa

Assignment Due: Wed, Feb 21, 11:59 PM

Name:

PID:

1.1 Instructions

- Review the academic integrity and collaboration policies on the course website.
- This assignment must be completed individually.
- All solutions must be written in this notebook.
- Math must be done in Markdown/LATEX.
- You must show your work and describe your solution.
- Programming aspects of this assignment must be completed using Python in this notebook.
- Your code should be well written with sufficient comments to understand, but there is no need to write extra markdown to describe your solution if it is not explictly asked for.
- This notebook contains skeleton code, which should not be modified (this is important for standardization to facilate efficient grading).
- You may use python packages for basic linear algebra, but you may not use functions that
 directly solve the problem. If you are uncertain about using a specific package, function, or
 method, then please ask the instructional staff whether it is allowable.
- You must submit this notebook as an .ipynb file, a .py file, and a .pdf file on Gradescope.
 - You may directly export the notebook as a .py file. You may use nbconvert to convert the
 .ipynb file to a .py file using the following command jupyter nbconvert --to script
 filename.ipynb
 - There are two methods to convert the notebook to a .pdf file.
 - * You may first export the notebook as a .html file, then print the web page as a .pdf file.
 - * If you have XeTeX installed, then you may directly export the notebook as a .pdf file. You may use nbconvert to convert a .ipynb file to a .pdf file using the following command jupyter nbconvert --allow-chromium-download --to webpdf filename.ipynb
 - You must ensure the contents in each cell (e.g., code, output images, printed results, etc.) are clearly visible, and are not cut off or partially cropped in the .pdf file.

- Your code and results must remain inline in the .pdf file (do not move your code to an appendix).
- While submitting on gradescope, you must assign the relevant pages in the .pdf file submission for each problem.
- It is highly recommended that you begin working on this assignment early.

1.2 Problem 1 (Programming): Estimation of the Camera Pose - Outlier rejection (20 points)

Download input data from the course website. The file hw3_points3D.txt contains the coordinates of 60 scene points in 3D (each line of the file gives the \tilde{X}_i , \tilde{Y}_i , and \tilde{Z}_i inhomogeneous coordinates of a point). The file hw3_points2D.txt contains the coordinates of the 60 corresponding image points in 2D (each line of the file gives the \tilde{x}_i and \tilde{y}_i inhomogeneous coordinates of a point). The corresponding 3D scene and 2D image points contain both inlier and outlier correspondences. For the inlier correspondences, the scene points have been randomly generated and projected to image points under a camera projection matrix (i.e., $\mathbf{x}_i = \mathbf{P}\mathbf{X}_i$), then noise has been added to the image point coordinates.

The camera calibration matrix was calculated for a 1280×720 sensor and 45° horizontal field of view lens. The resulting camera calibration matrix is given by

$$\mathbf{K} = \begin{bmatrix} 1545.0966799187809 & 0 & 639.5 \\ 0 & 1545.0966799187809 & 359.5 \\ 0 & 0 & 1 \end{bmatrix}$$

For each image point $\mathbf{x} = (x, y, w)^{\top} = (\tilde{x}, \tilde{y}, 1)^{\top}$, calculate the point in normalized coordinates $\hat{\mathbf{x}} = \mathbf{K}^{-1}\mathbf{x}$.

Determine the set of inlier point correspondences using the M-estimator Sample Consensus (MSAC) algorithm, where the maximum number of attempts to find a consensus set is determined adaptively. For each trial, use the 3-point algorithm of Finsterwalder (as described in the paper by Haralick et al.) to estimate the camera pose (i.e., the rotation R and translation t from the world coordinate frame to the camera coordinate frame), resulting in up to 4 solutions, and calculate the error and cost for each solution. Note that the 3-point algorithm requires the 2D points in normalized coordinates, not in pixel coordinates. Calculate the projection error, which is the (squared) distance between projected points (the points in 3D projected under the normalized camera projection matrix $\hat{P} = [R \mid t]$) and the measured points in normalized coordinates (hint: the error tolerance is simpler to calculate in pixel coordinates using $P = K[R \mid t]$ than in normalized coordinates using $\hat{P} = [R \mid t]$. You can avoid doing covariance propagation). There must be at least 40 inlier correspondences.

Hint: this problem has codimension 2.

Report your values for:

- the probability p that as least one of the random samples does not contain any outliers
- the probability α that a given point is an inlier
- the resulting number of inliers
- the number of attempts to find the consensus set

```

toc = time.time()
time_total = toc - tic
# display the results
print(f'took {time total} secs')
print('R_linear = ')
print(P_linear[:, 0:3])
print('t_linear = ')
print(P_linear[:, -1])
```

1.4 Problem 3 (Programming): Estimation of the Camera Pose - Nonlinear Estimate (30 points)

Use R_{linear} and t_{linear} as an initial estimate to an iterative estimation method, specifically the Levenberg-Marquardt algorithm, to determine the Maximum Likelihood estimate of the camera pose that minimizes the projection error under the normalized camera projection matrix $\hat{P} = [R \mid t]$. You must parameterize the camera rotation using the angle-axis representation ω (where $[\omega]_{\times} = \ln R$) of a 3D rotation, which is a 3-vector.

Report the initial cost (i.e., cost at iteration 0) and the cost at the end of each successive iteration. Show the numerical values for the final estimate of the camera rotation $\omega_{\rm LM}$ and $R_{\rm LM}$, and the camera translation $t_{\rm LM}$.

```
